1. Introduction

This report presents all the XBT data collected in association with the launching of 76 RAFOS floats in the Gulf Stream east of Cape Hatteras as part of the SYNOP (SYNoptic Ocean Prediction) experiment. The floats and XBTs were deployed during the period April 1988 through February 1990 by Capt. David Murphy of the H.O.S. *Bold Venture*, a commercial freighter operating between Norfolk, Virginia and Bermuda. From the end of January to the beginning of April 1988, six RAFOS floats (also part of the SYNOP experiment) were launched which failed to return any useful data due to a programming error in the floats. The XBT data associated with those floats are also included in this report. The RAFOS float data are summarized in a previous data report (Anderson-Fontana et al., 1991). The XBTs were taken to determine the launch site for each float in the axis of the Gulf Stream, identified as the point at which the 15°C isotherm crosses 450 meters.

2. Technical Summary

Sippican T7 probes, with a nominal depth of 760 m, were used. The acquisition equipment consisted of a stern deck launcher, a BathySystems XBT deck unit, and an HP-85B computer. The raw data were stored on HP data cartridges and later transferred to a Concurrent computer via an RS-232 cable for processing. The XBTs (and associated floats) were launched in the vicinity of 36°N and 73°W while the freighter steamed along a NW-SE line across the Gulf Stream. When the XBT trace showed the 15°C isotherm at approximately 450 m, defined as the axis of the Stream, the RAFOS float was launched. Figure 1 shows an average thermal cross-section of the Gulf Stream. As the Stream is crossed from NW to SE the thermal structure deepens, and conversely, the isotherms rise when crossing from SE to NW. While the average structure may differ from the actual profile of the Stream at a given time, it is generally simple enough to allow the anticipation of the approximate launch site in advance. Typically, two to four XBTs were used to determine the actual launch site.

The raw voltages were converted into depth and temperature pairs using the Sippican-

provided algorithms. The XBT depths have not been adjusted for the 4.5% fall rate error that has been reported (Watts et al., 1990). Measurements shallower than 2 m and deeper than 810 m were deleted to remove data points outside the XBT's intended operating range. The data were then filtered using a median filter. Sampling was done every 0.1 s (approximately 0.6 m), with smoothing over five data points, resulting in a vertical resolution of about 3 m. A tolerance of 0.1°C was used, the median value replacing the measured value where the difference between the two was greater than the tolerance. These replaced data points are flagged with an asterisk in the archived files.

3. Discussion

Figure 2 shows the locations of all XBTs launched as part of the SYNOP experiment. A solid line connects the XBT launch sites associated with each RAFOS float. In most cases, the ship was steaming from west to east with a heading between 100° and 110°. A total of 214 XBTs were launched, summarized in Table 1. The data files for 11 of these were unavailable, so only launch positions are known. The locations of those XBTs launched immediately prior to the deployment of RAFOS floats are shown in figure 3. As previously stated, the floats were deployed as closely as possible to where the 15°C isotherm was at a depth of 450 m, defined to be the axis of the Gulf Stream. For each float deployment, the depths of the 15°C isotherm as determined from the associated XBTs were used to calculate first the slope of the isotherm, and then the exact location of the Gulf Stream axis (as previously defined) at the time of deployment. For float launches with only one XBT, the axis location was calculated using an estimated isotherm slope based on surrounding values and an average ship's heading of 105°. A bar graph of distance from the axis (figure 4) shows that most of the floats were launched very close to the axis. Excluding the one outlying data point at approximately 50 km, the mean distance between the Gulf Stream axis and final XBT launch position is 1.4 km with a standard deviation of 7.6 km. The negative distances correspond to floats launched north (shoreward) of the axis. Figure 5a shows the calculated axis positions for all float launches (excluding those seven associated with the XBTs for which there were

no data), covering the period of time from January 1988 through the beginning of February 1990. Figures 5b and 5c cover the periods January 1988 through December 1988 and January 1989 through the beginning of February 1990, respectively. During most of this time, the Gulf Stream axis near 36°N was located between 73° and 74°W . Those launches east of 73°W in figure 5c are from the period September and October 1989. This is in agreement with satellite imagery during these dates, which showed the Gulf Stream to be farther east than at other times throughout the period of interest.

To further examine the variability in the Gulf Stream axis position during this period of time, the calculated axis positions were compared to estimated mean paths of the Stream in the XBT launch region. A bearing of 56°T was used, as determined from Halkin et al., 1985. After looking at several mean paths with this bearing, a best estimate was chosen which intersected 74°W at 35.75°N , shown superimposed on the axis positions in figure 6. Figure 7 is a plot of the distance of the calculated axis locations projected to the mean axis vs. yearday from the end of January 1988 through the beginning of February 1990. The "yearday" axis is actually yearday + 366 for 1989 (1988 was a leap year) and yearday + 731 for 1990. The eight points between days 600 and 655 correspond to September and October 1989 when the Gulf Stream axis was farther east; those at 666 and 743 correspond to the two launches south of 35°N and west of 74°W (see figure 5a), where the axis orientation of 56° would be inaccurate. Deleting these ten data points, all greater than 40 km from the estimated mean axis, results in a mean distance of 2.0 km with a standard deviation of 17.8 km. The data files for those XBTs launched from mid-January 1989 through the beginning of April 1989 are missing, corresponding to the gap in the plot approximately between days 380 and 470 (a total of seven out of 82 float launches). As in figure 4, negative distances correspond to those points north (shoreward) of the Stream axis. Other than in the early fall of 1989, as previously noted, there was little variation in the Gulf Stream axis location in the region of the XBT launches.

The next section contains the individual XBT plots arranged according to launch number, referenced in Table 1. The numbering is sequential, and any missing XBTs either were not

launched (12, 29, 30, 60) or were launched as tests near the shore of Cape Hatteras (10, 11, 31-35). The raw data files for XBTs 73 and 104 through 111 are missing, so only the launch information is known. The temperature and depth scales are all 0-30°C and 0-800 m, respectively. The XBT launches are also cross-referenced to the RAFOS float launches (Table 1). The first 28 XBTs correspond to the six floats in early 1988 that did not return any data. XBTs 124, 125 and 126 were launched on the Sargasso Sea side of the Gulf Stream after the launch of float 198; 42, 188 and 193 were launched independent of any floats. The reader should note that the data have been conservatively edited, and depending on the application of the data, further examination and editing may be required.

4. Acknowledgements

We thank Capt. David Murphy of the *Bold Venture* for his support and cooperation in the launching of the XBTs, recording of the data, and prompt return of the launch information and data tapes to us. We extend our appreciation to him for his precise launching of the RAFOS floats in the axis of the Gulf Stream. Mr. Jim Fontaine was responsible for establishing and maintaining the excellent cooperation between the University of Rhode Island and Capt. Murphy. Support for this project was provided by the Office of Naval Research under grants N00014-87-K-0235 and N00014-90-J-1602.

Note: Float 119 (XBTs 89 through 92) was inadvertently excluded from the SYNOP float data report (Anderson-Fontana et al., 1991). However, it either didn't surface or failed to transmit after surfacing, so no data were returned. Raw data files for XBTs 73 and 104 through 111 are not available.

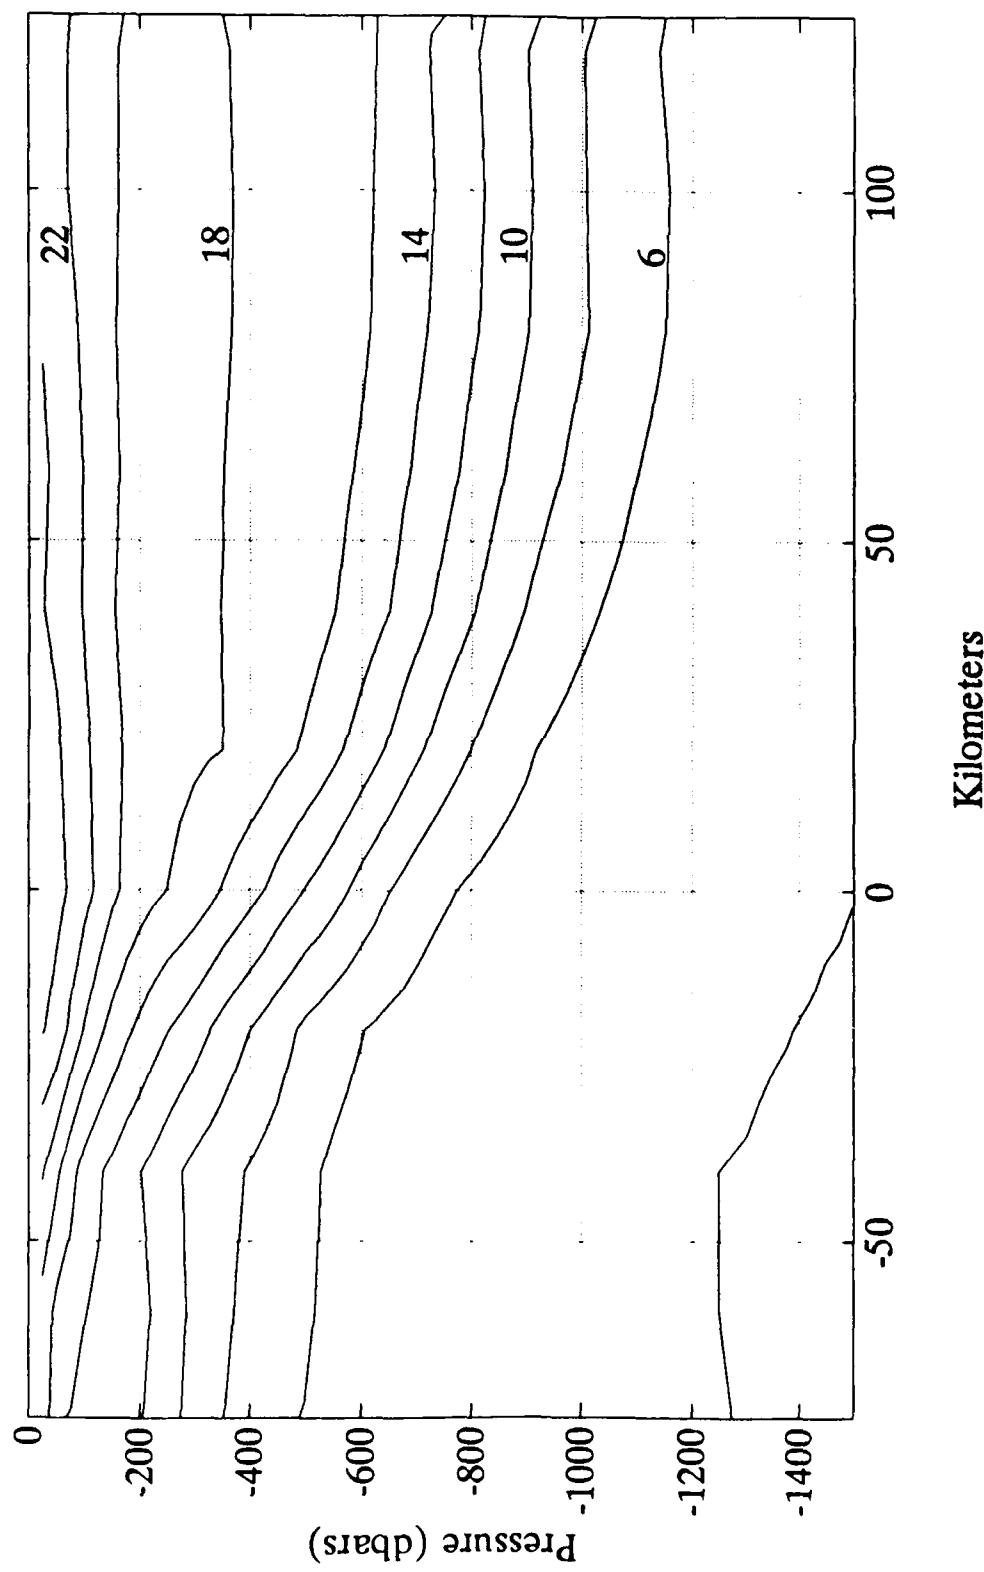

Fig. 1. Average thermal cross section of the Gulf Stream, as viewed looking downstream (adapted from Halkin et al. [1985], the origin being defined as the location halfway between where the 12°C isotherm crossed 400 m and where it crossed 600 m). Isotherms are labeled every 4°C.

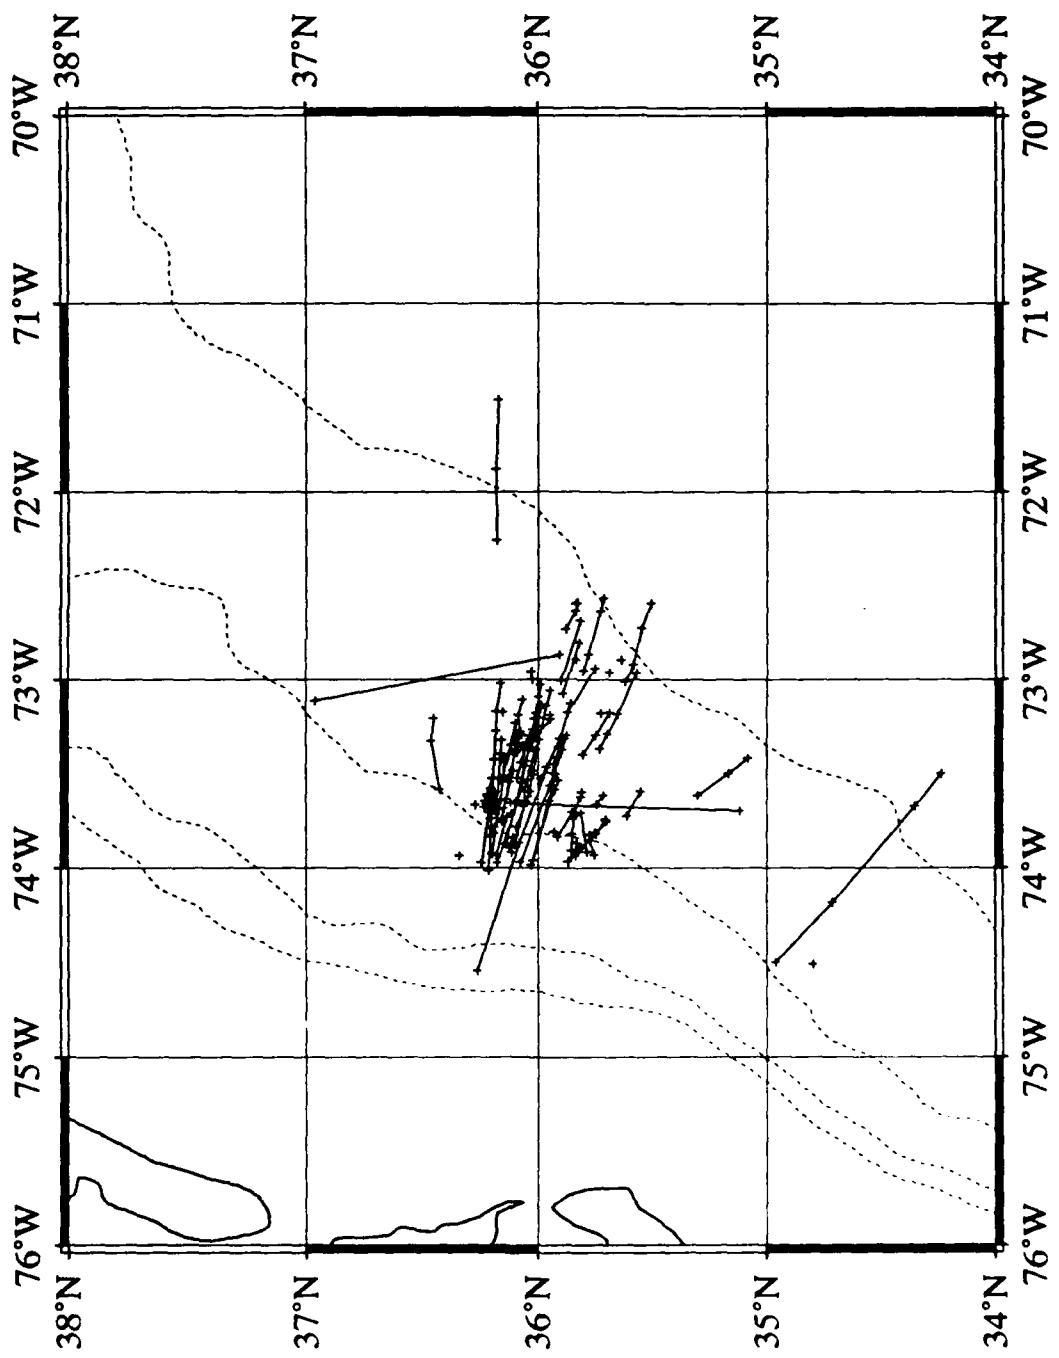

Fig. 2. Locations of all XBT's launched as part of the SYNOP experiment. Each solid line connects those XBT launch sites associated with a single RAFOS float deployment (with the exception of the three XBT's launched in the Sargasso Sea near 72°W). The dashed contour lines represent 1000, 2000, 3000 and 4000 meters.

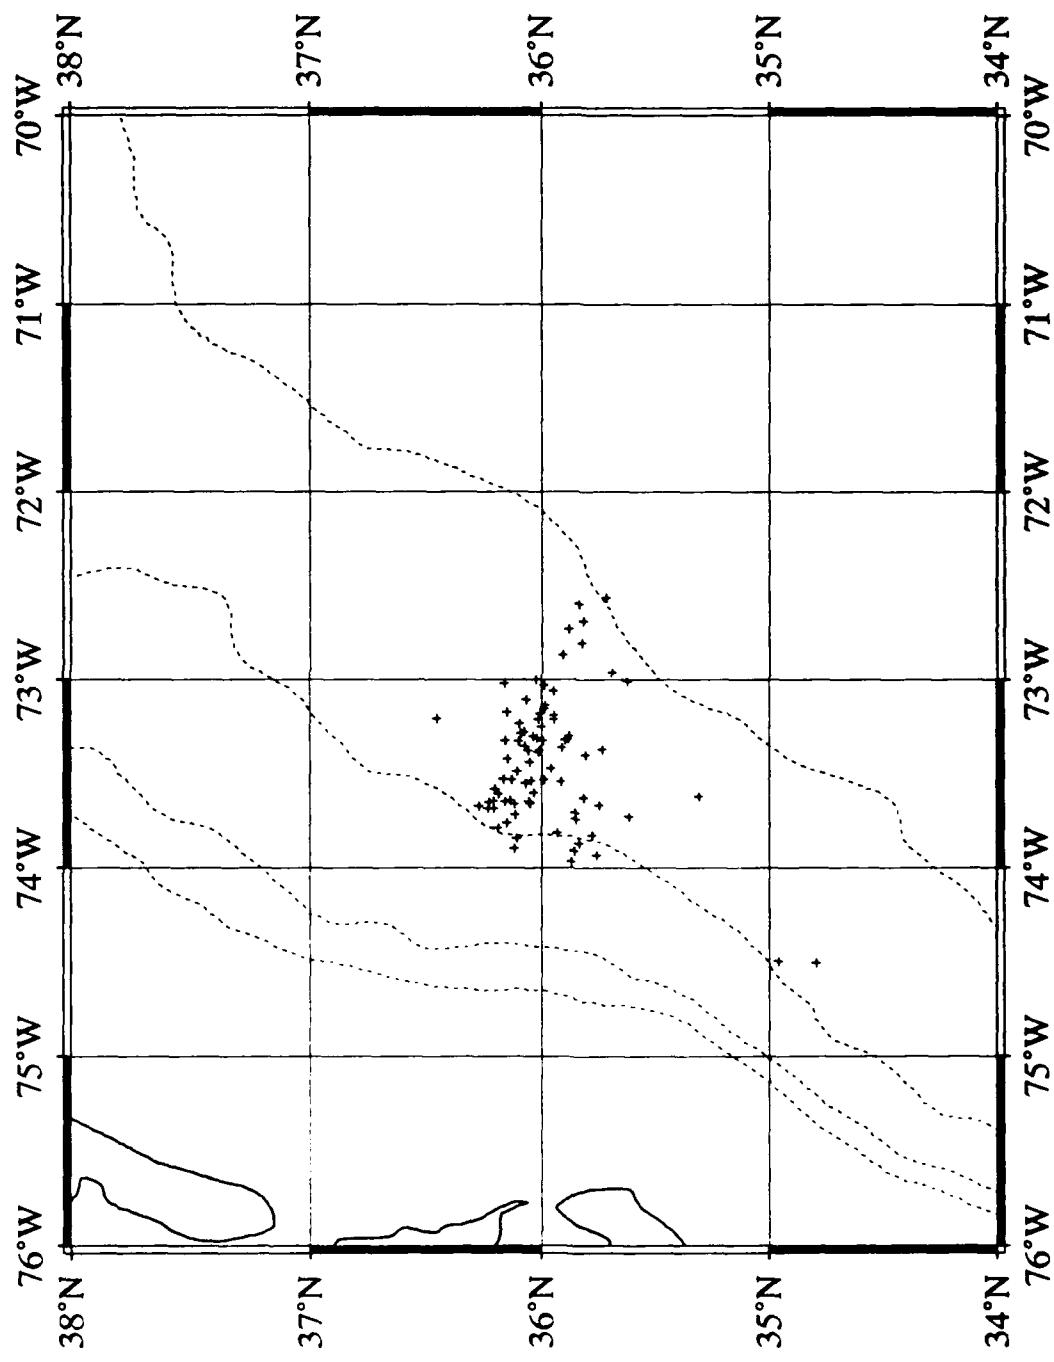

Fig. 3. Locations of those XBTs launched just prior to the deployment of the RAFOS floats. The float deployment sites were chosen where the 15°C isotherm intersected 450 m as shown by the XBTs.

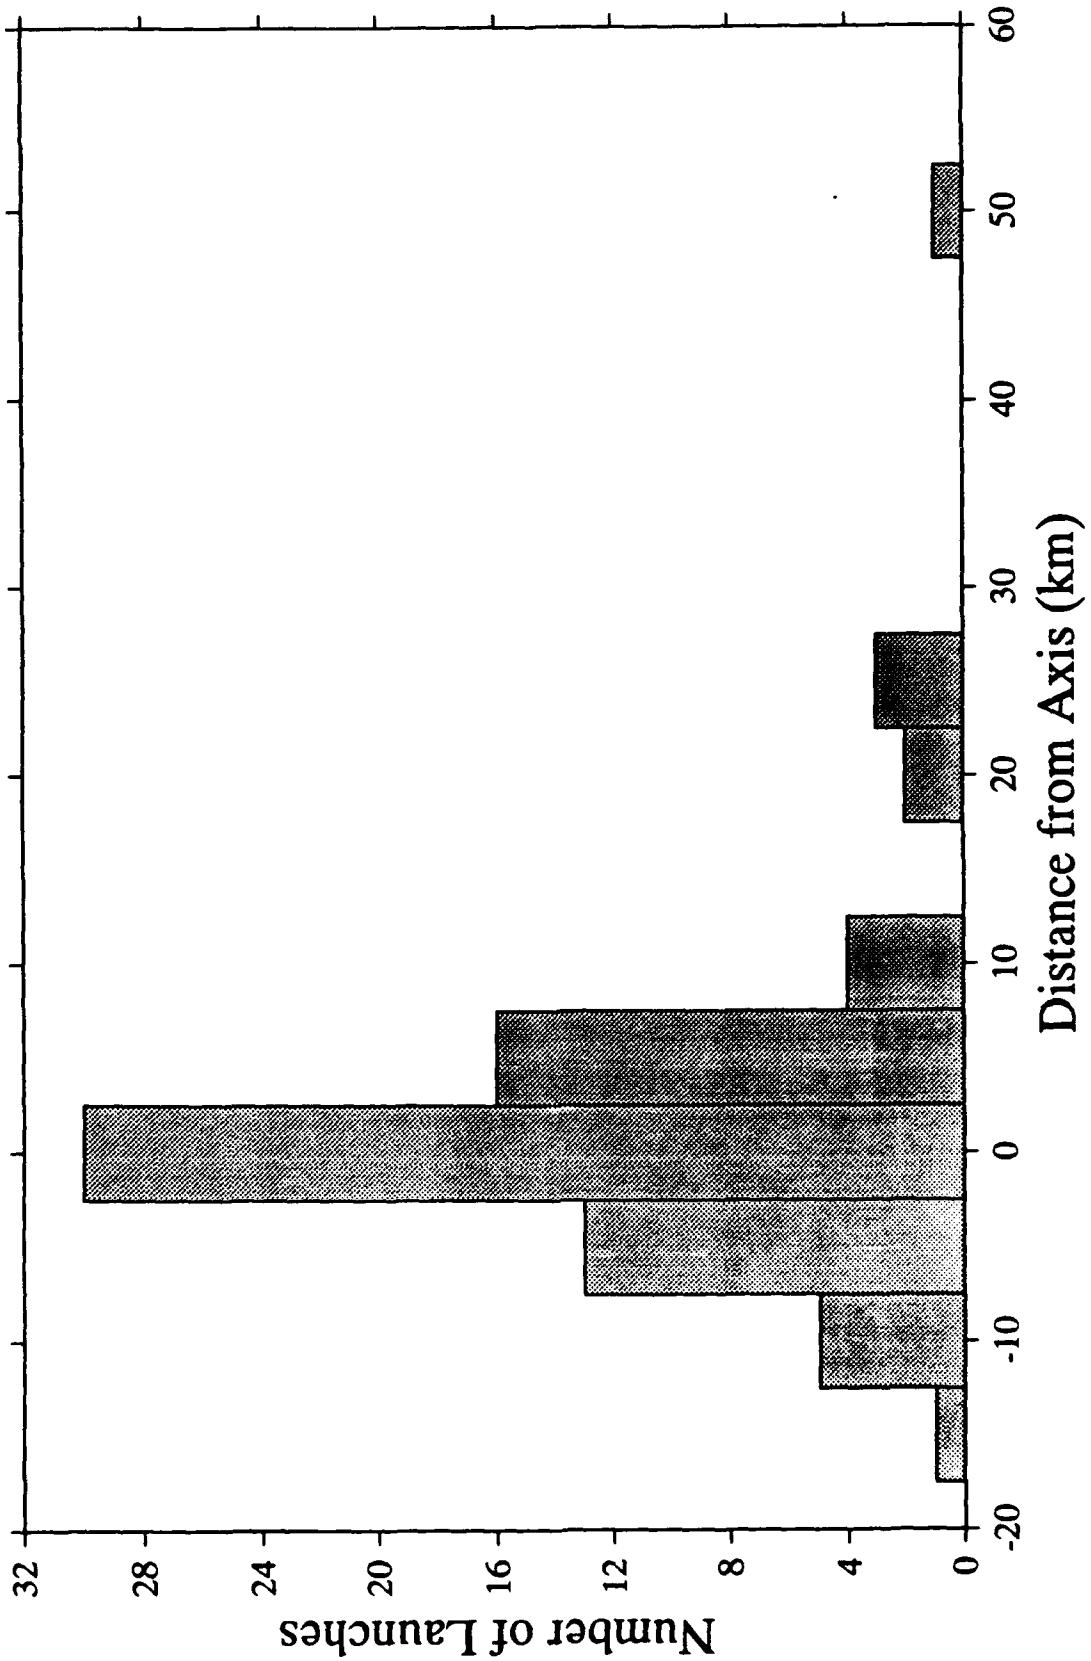

Fig. 4. Bar graph showing distances of the XBT launch sites in figure 3 from the Gulf Stream axis location calculated for each site. Negative distances correspond to sites north (shoreward) of the Stream axis. Excluding the one outlying data point at 50 km, the mean distance is 1.4 km with a standard deviation of 7.6 km.

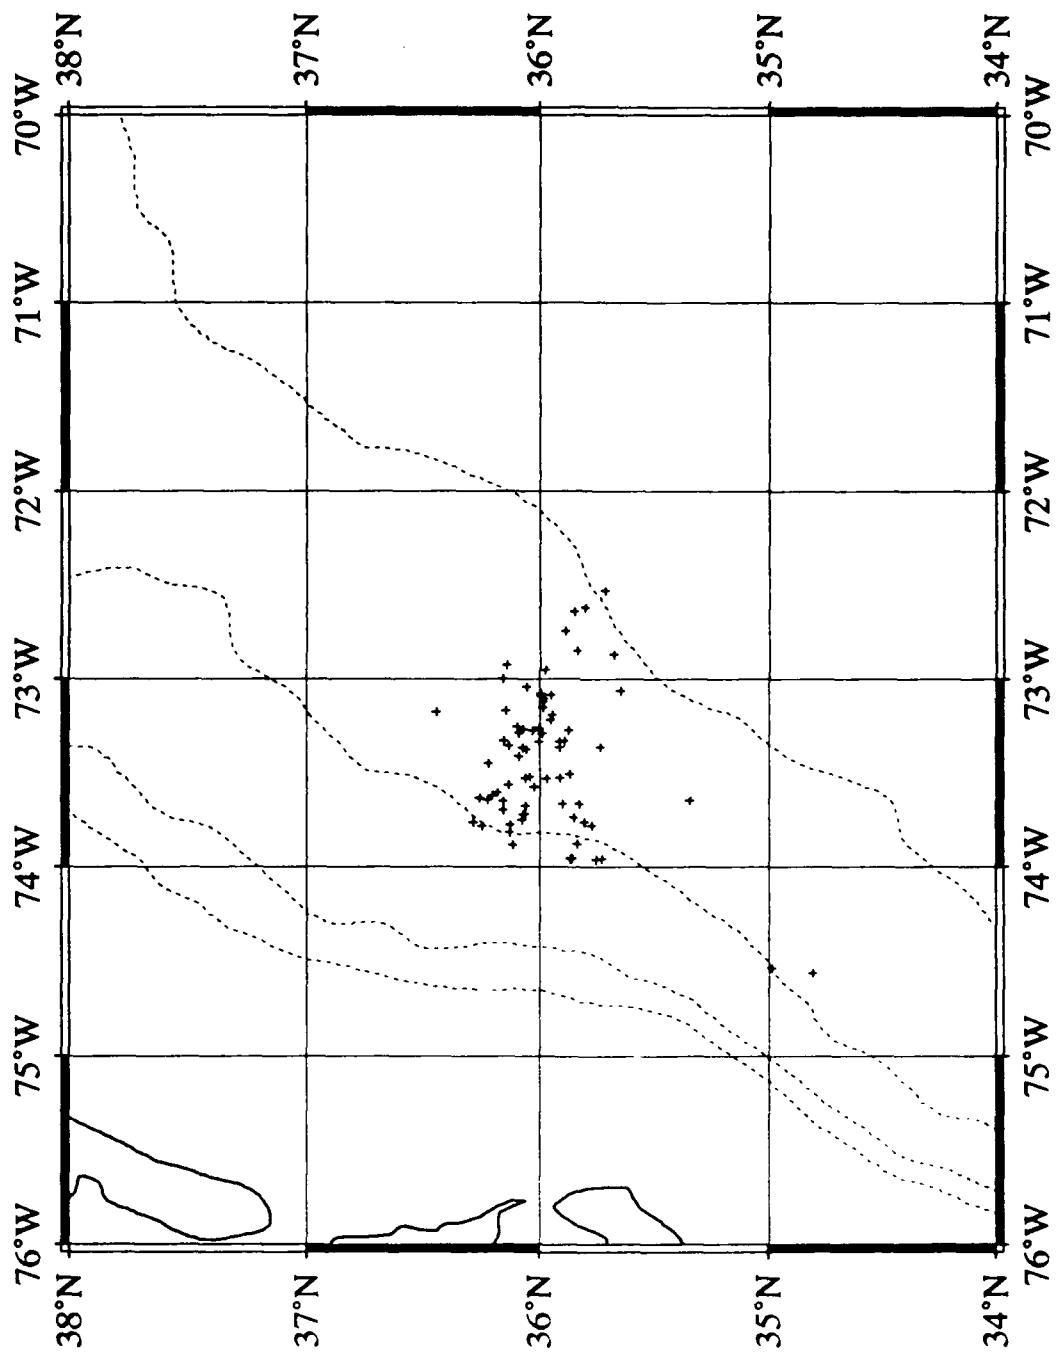

Fig. 5a. Calculated Gulf Stream axis positions at the times of all RAFOS float launches (excluding those seven associated with the XBTs for which there were no data available), from January 1988 through the beginning of February 1990.

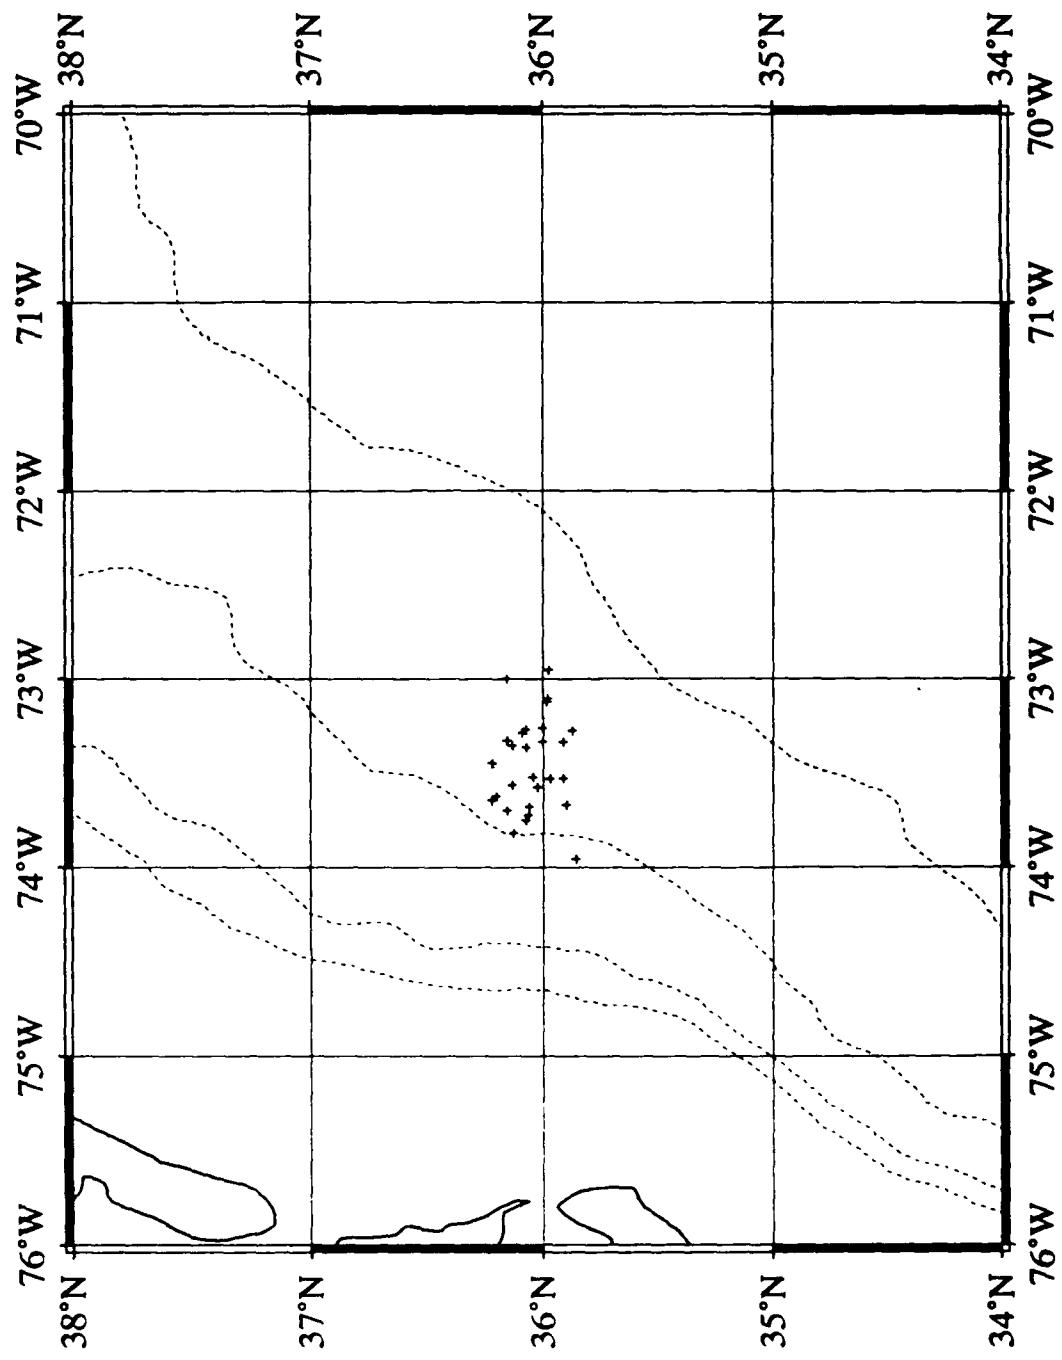

Fig. 5b. Calculated Gulf Stream axis positions as in figure 5a, covering January 1988 through December 1988.

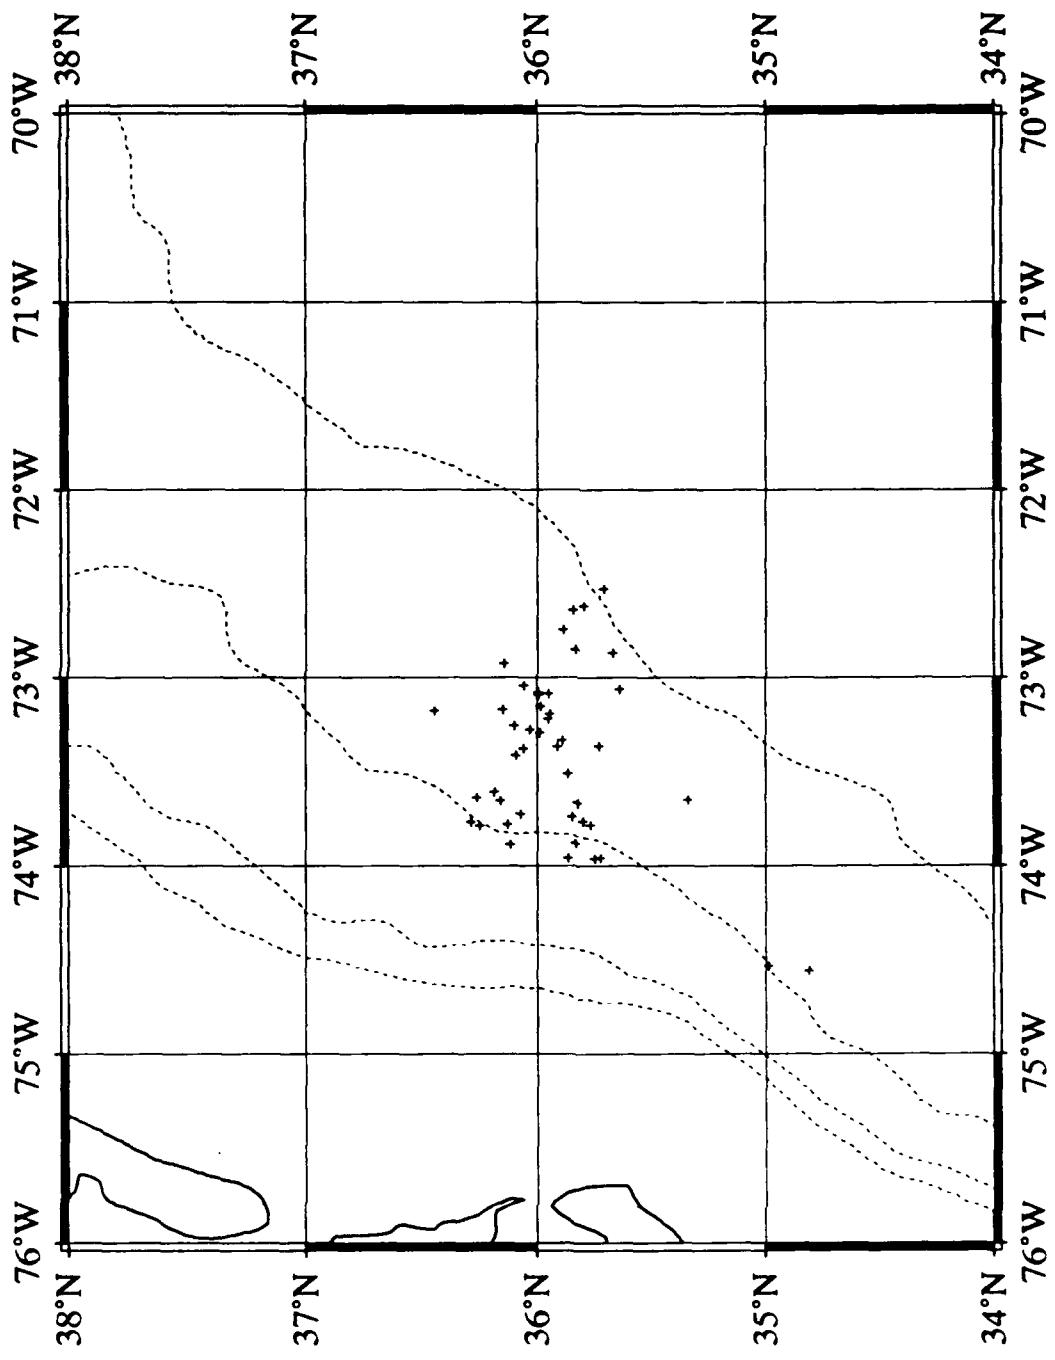

Fig. 5c. Calculated Gulf Stream axis positions as in figures 5a and 5b, covering January 1989 through the beginning of February 1990.

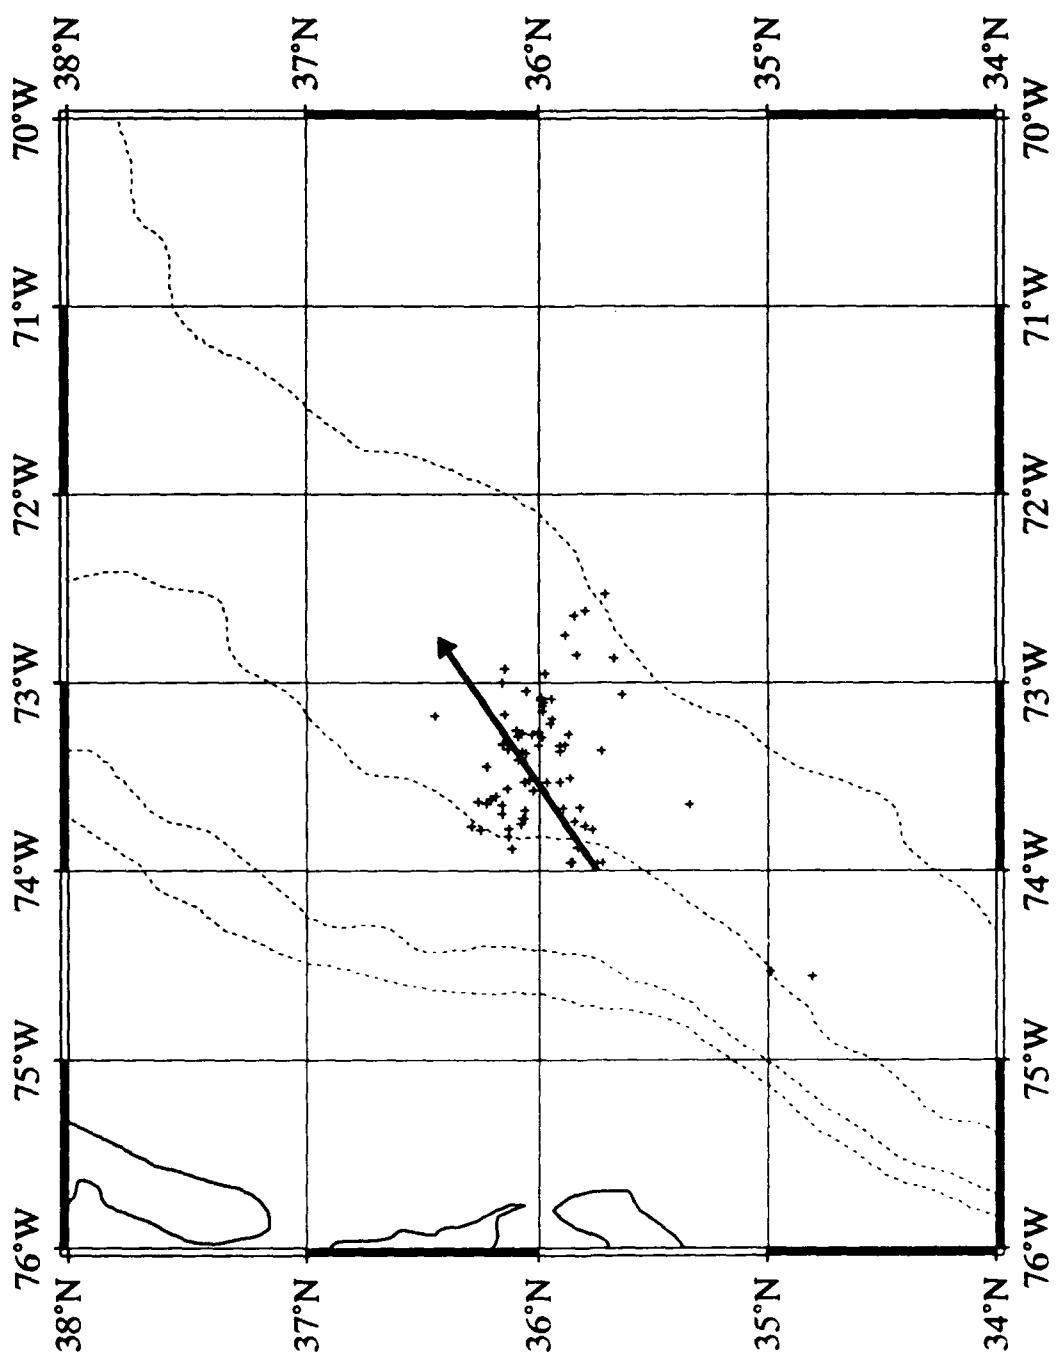

Fig. 6. Estimated mean path of the Gulf Stream superimposed on the calculated axis positions from figure 5a.

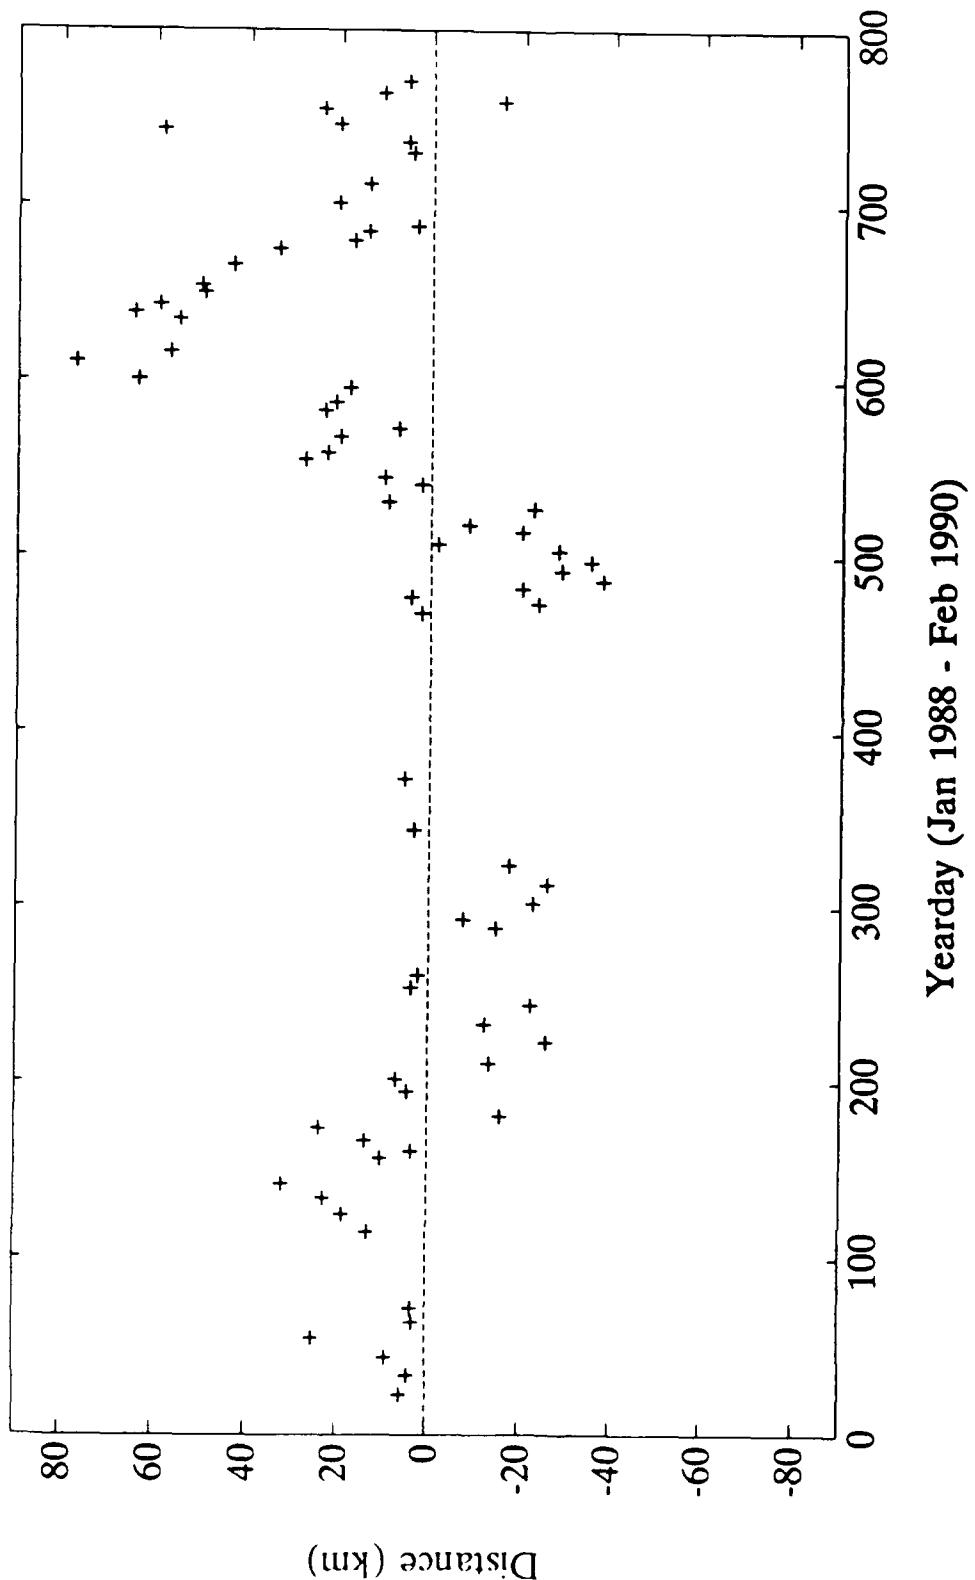

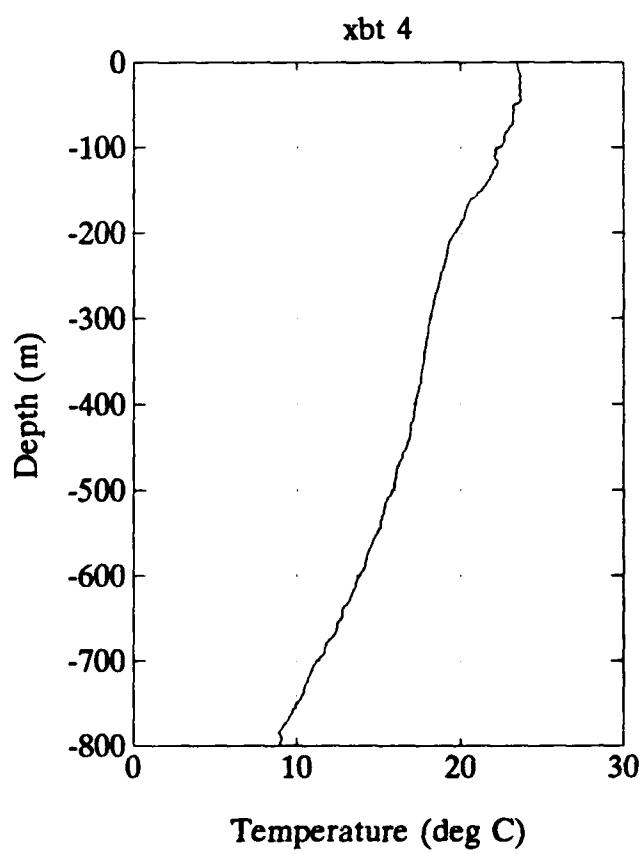

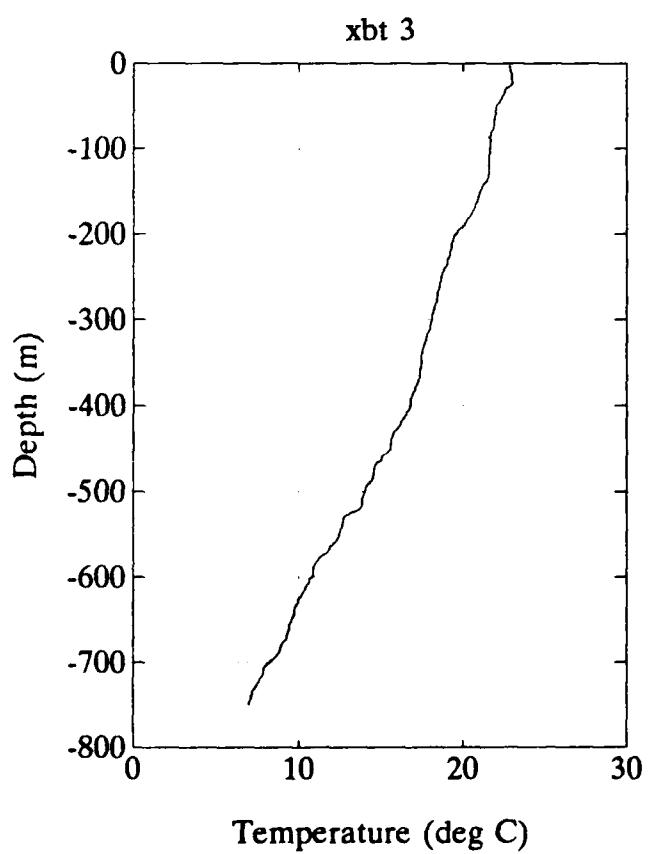

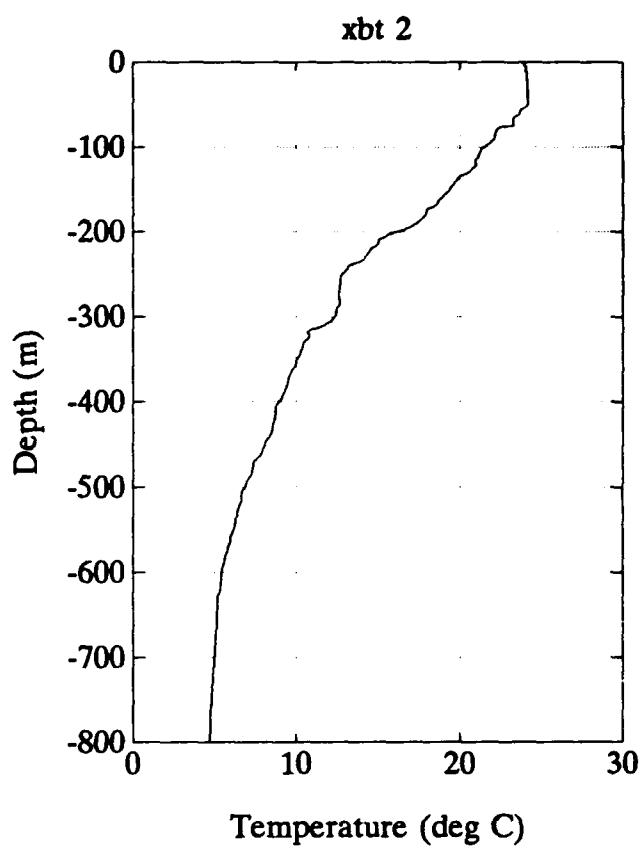

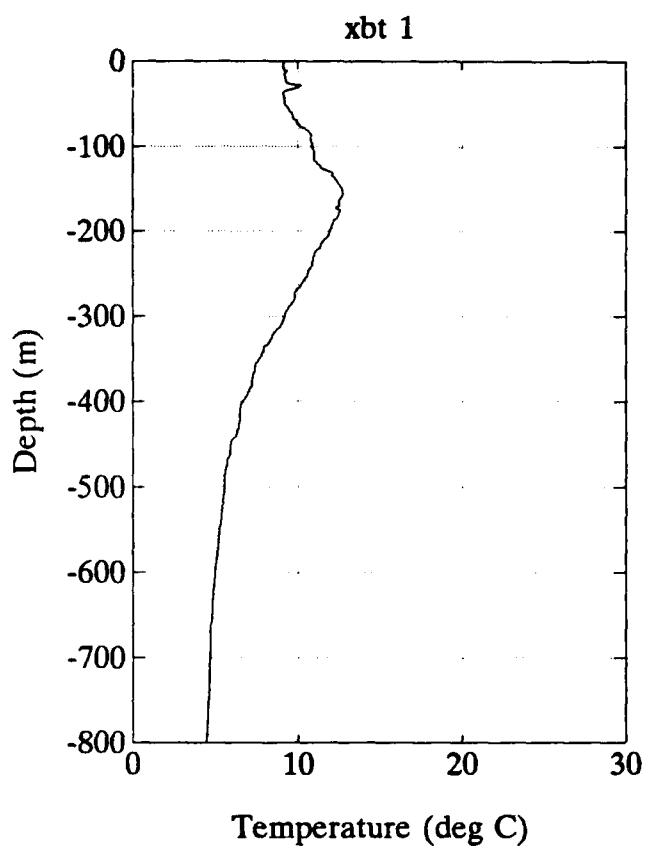

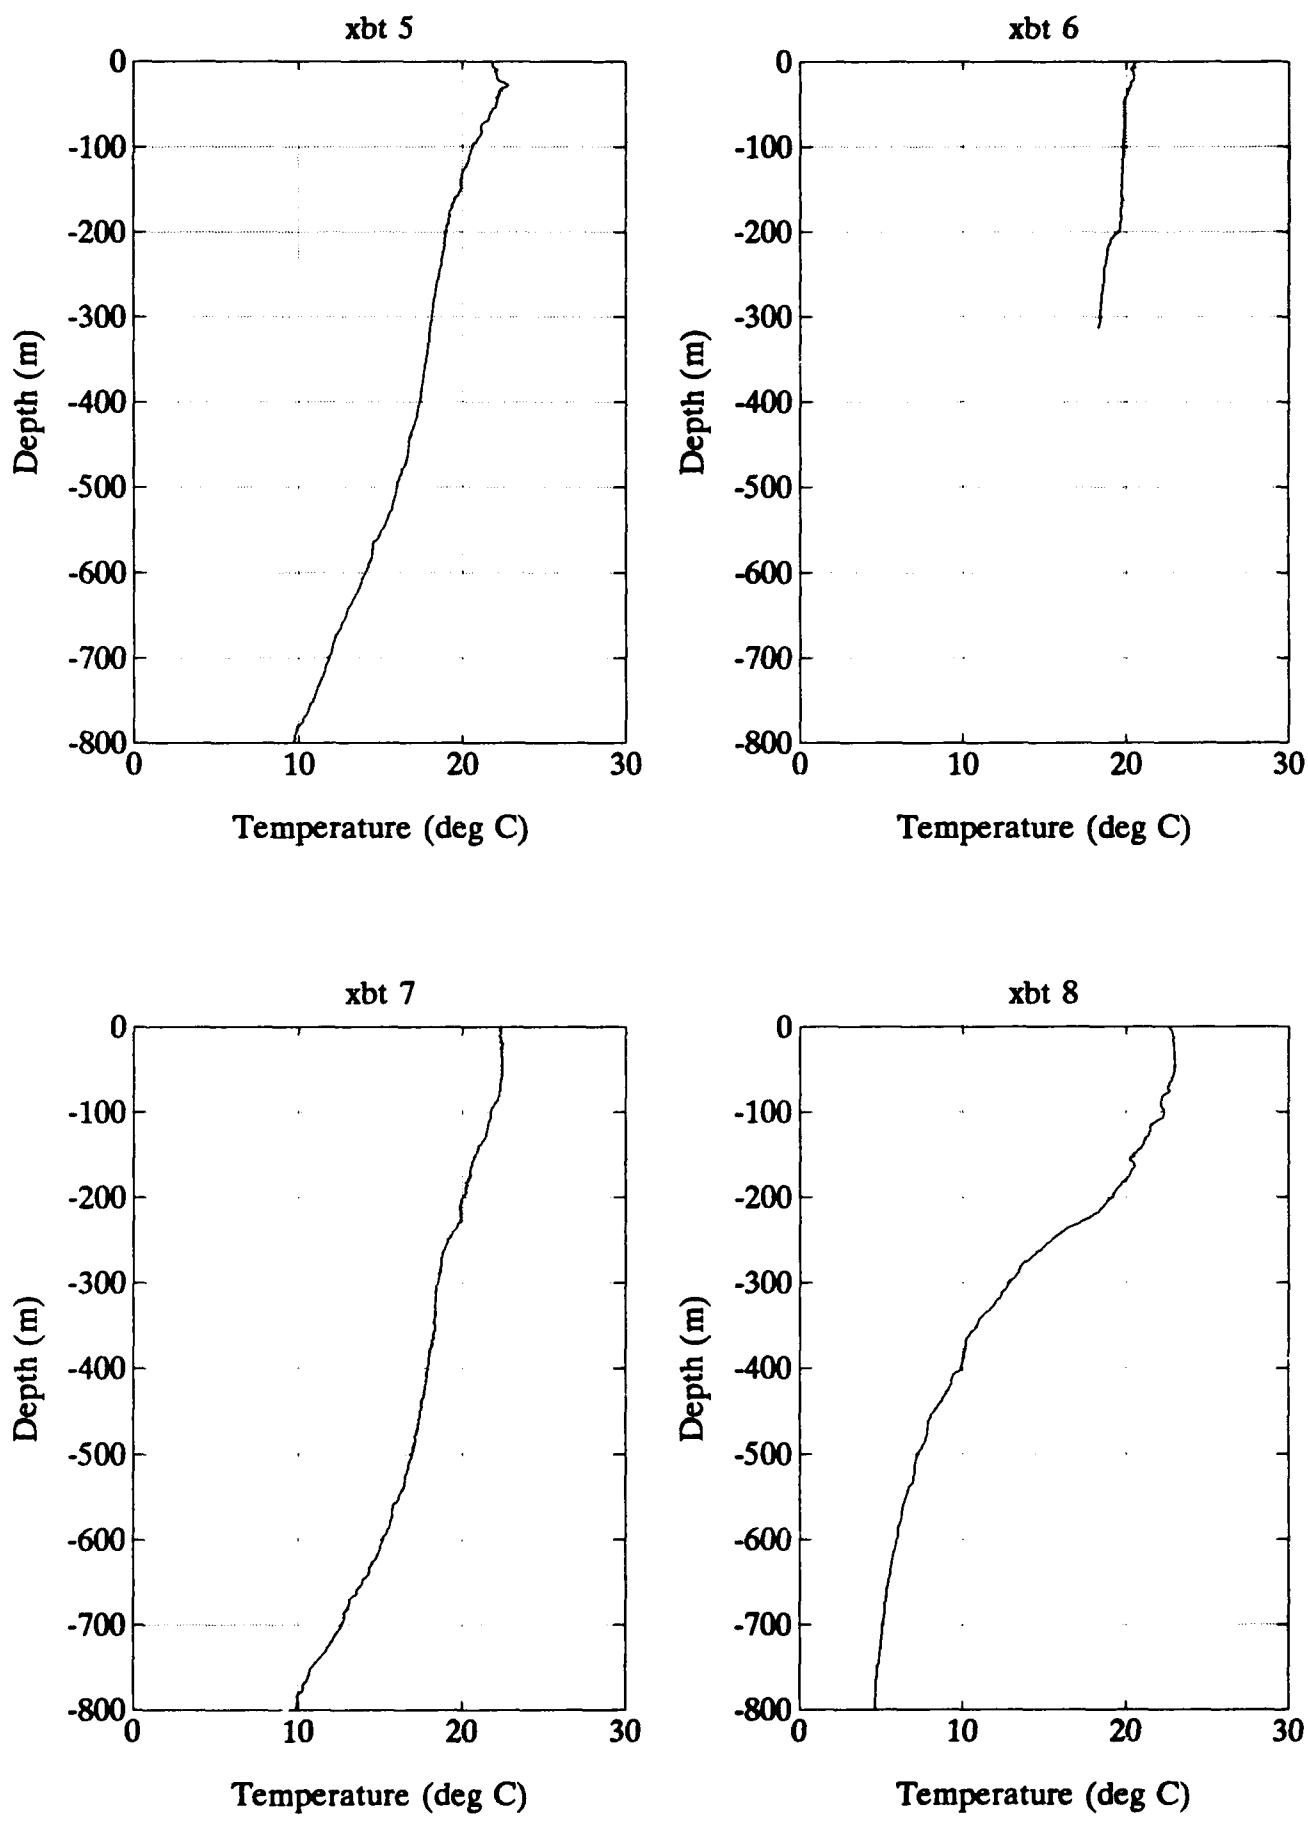

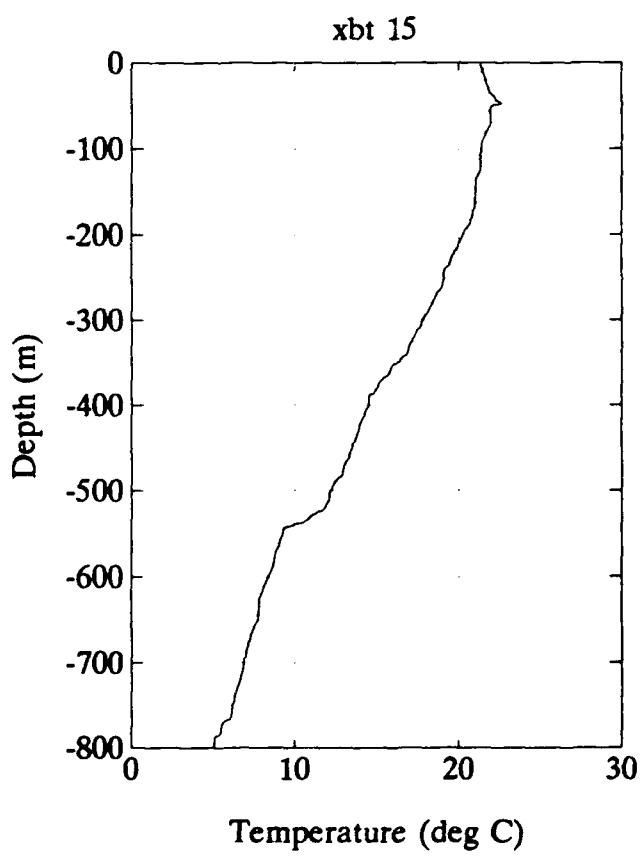

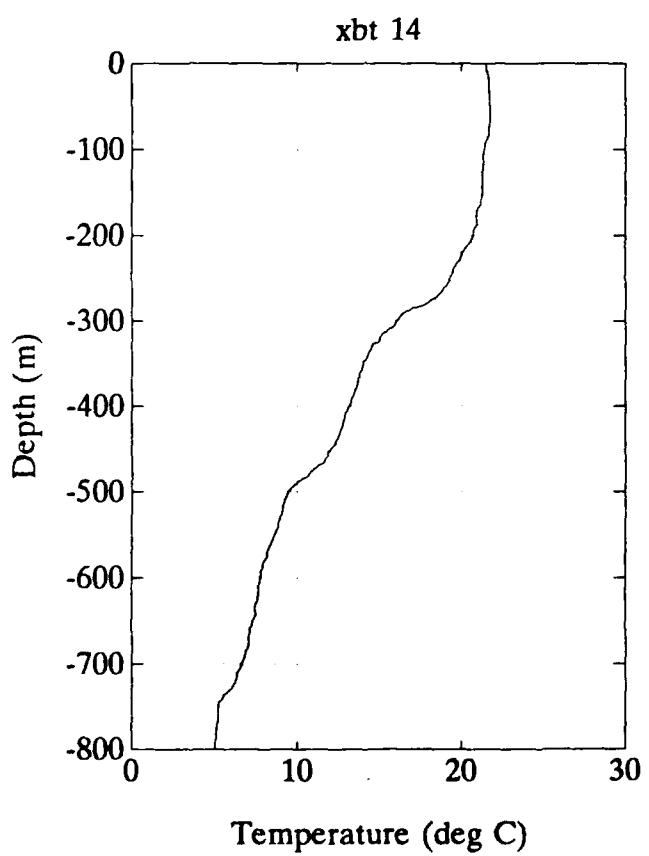

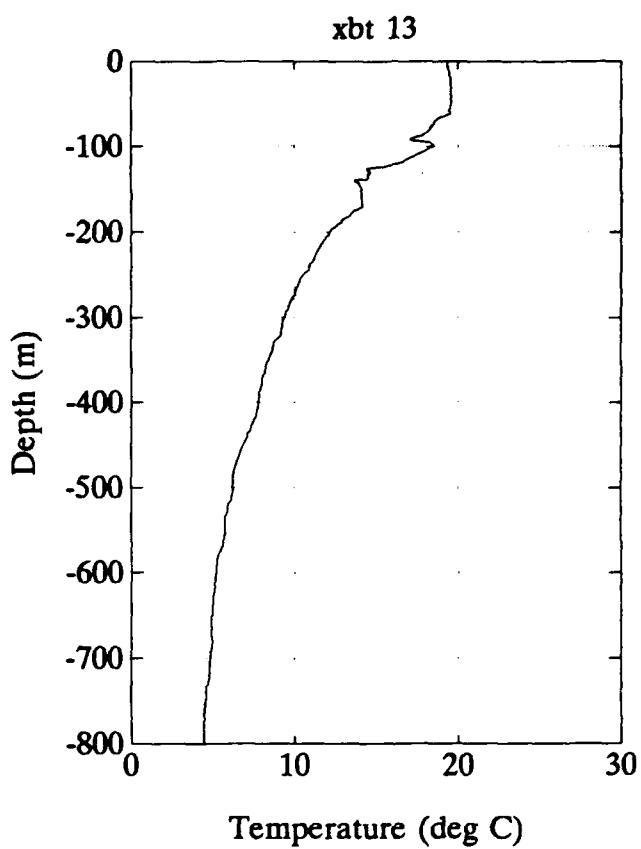

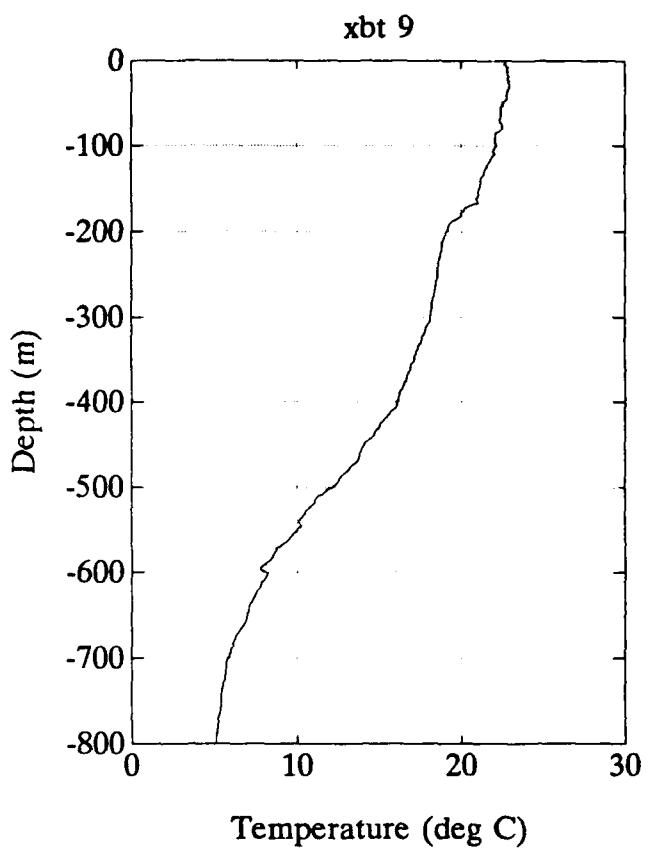

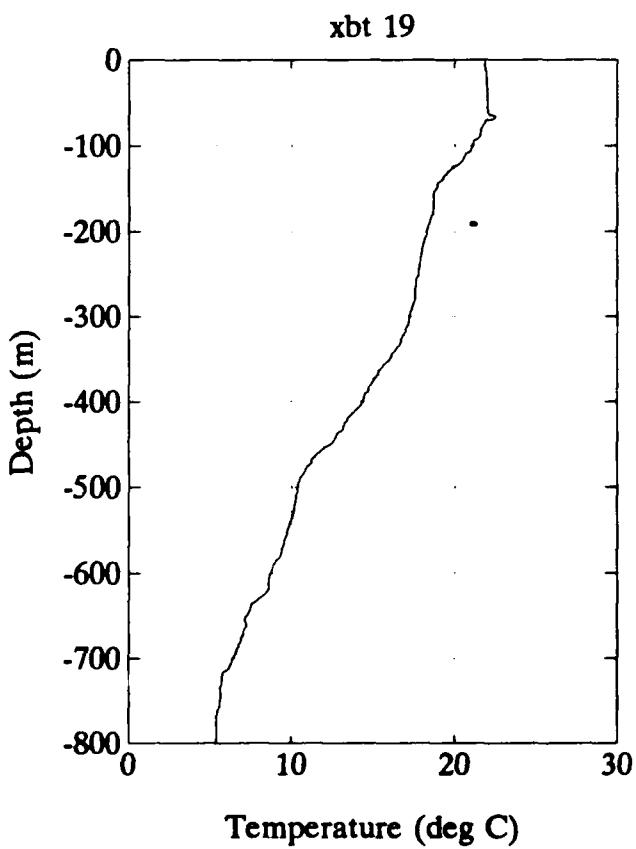

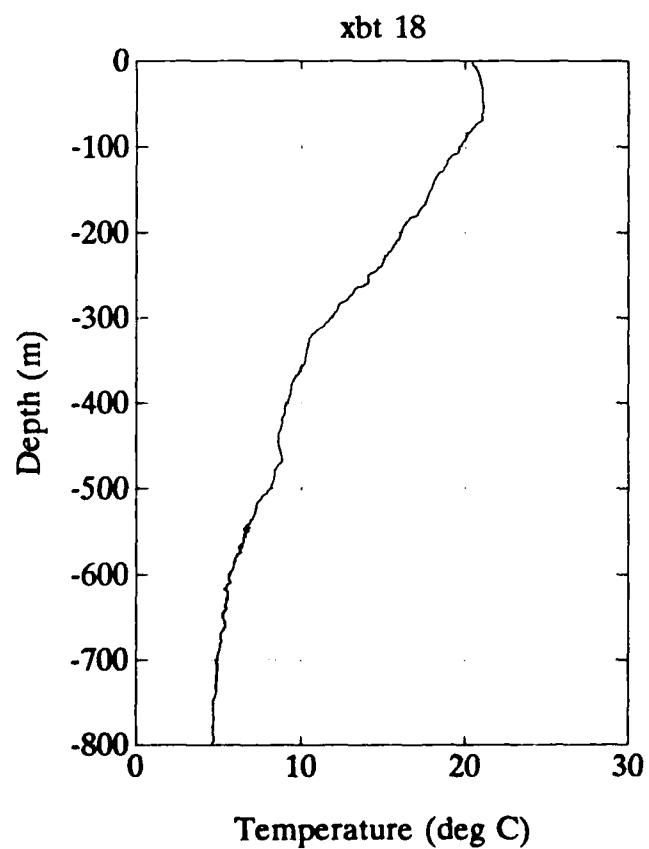

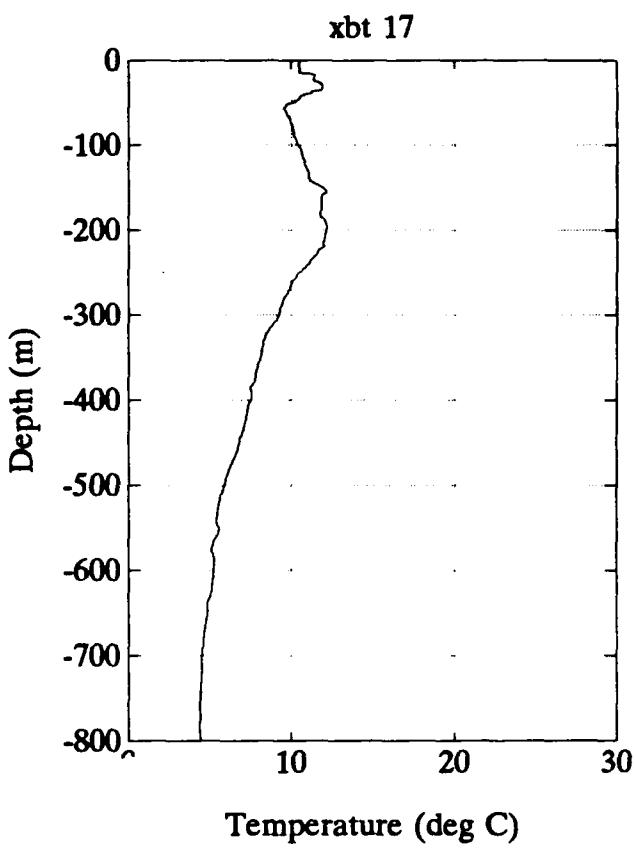

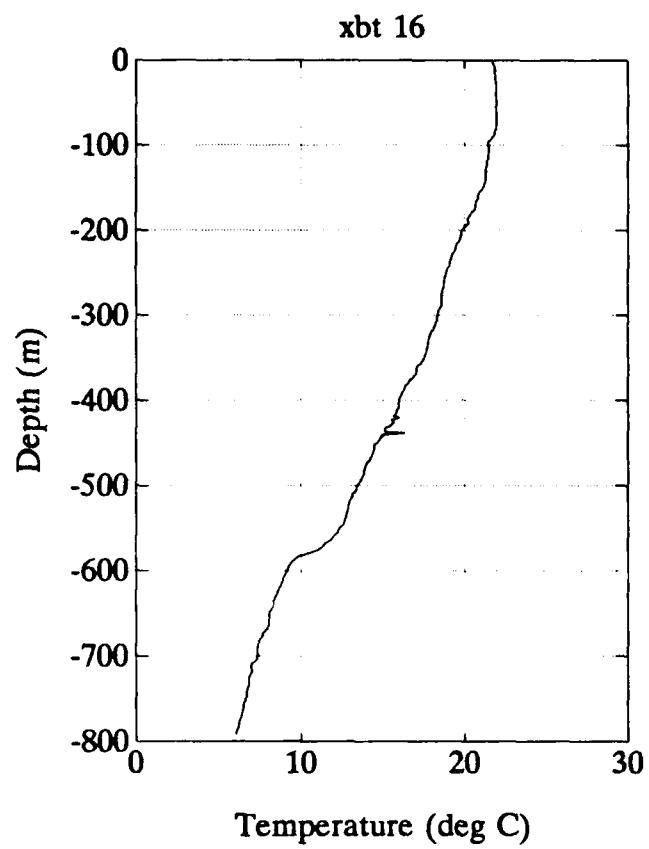

Fig. 7. Distances of the calculated axis locations projected to the mean Gulf Stream axis shown in figure 6 vs. yearday from January 1988 through the beginning of February 1990. The "yearday" axis is yearday + 366 for 1989 and yearday + 731 for 1990. The gap between days 380 and 470 is due to missing XBT data files. Negative distances are north (shoreward) of the axis, as in figure 4.

19. ABSTRACT (Continue on reverse if necessary and identify by block number) From the end of January 1988 to February 1990, 214 XBTs were deployed in the Gulf Stream as part of the SYNOP experiment. The XBTs were used to determine the launch sites for a total of 82 RAFOS floats in the axis of the Gulf Stream, identified as the point at which the 15°C isotherm crosses 450 meters. Two to four XBTs were typically used to determine each float launch site. This report presents all the SYNOP XBT data, and examines the variability in the Gulf Stream axis position during this period of time.
